

Introduction to machine-learning using scikit-learn

QLSC612

May 2026

By

Nikhil Bhagwat & Mohammad Torabi

Objectives

- Part 2: Unsupervised learning
 - **Dimensionality reduction**
 - Clustering
 - *Coding example: PCA, k-means*
 - *Coding example: fMRI site prediction*

How do I validate my design choices?

Model fitting →
the easy part!

X

Y

Which features?

Which model?

Which performance metrics?

Unsupervised learning

- Learning without knowing the true labels
- Objectives
 - Dimensionality reduction of features
- Techniques
 - Feature Transformation/Projection

Dimensionality Reduction

Data is almost 1-dimensional
BUT represented as
2-dimensional

Dimensionality Reduction

- High dimensional data:
 - Model complexity increases -> unstable solution
 - Risk of overfitting: fitting exactly training data but failing on test data

Dimensionality Reduction

- **Curse of Dimensionality:** large number of input features can dramatically impact the performance of ML algorithms
- Techniques:
 - Feature selection (usually supervised)
 - Feature transformation (usually unsupervised)

Feature Transformation vs. Feature Selection

Maybe OK to drop X_2

Data is low-dimensional BUT
no feature can be dropped

Feature Selection

$$\hat{y} = \mathbf{X} \hat{\beta}$$

Feature Selection

$$\hat{\mathbf{y}} = \mathbf{X} \hat{\boldsymbol{\beta}}$$

The diagram illustrates the feature selection process in a linear model. It shows the relationship between the target vector $\mathbf{y}$, the predicted vector $\hat{\mathbf{y}}$, the feature matrix $\mathbf{X}$, and the coefficient vector $\hat{\boldsymbol{\beta}}$.

The target vector $\mathbf{y}$ and the predicted vector $\hat{\mathbf{y}}$ are represented by red vertical bars. The feature matrix $\mathbf{X}$ is represented by a set of vertical bars of different colors (red, blue, orange, green). The coefficient vector $\hat{\boldsymbol{\beta}}$ is represented by a set of small gray squares.

The equation $\hat{\mathbf{y}} = \mathbf{X} \hat{\boldsymbol{\beta}}$ is shown. The predicted vector $\hat{\mathbf{y}}$ is approximately equal to the product of the feature matrix $\mathbf{X}$ and the coefficient vector $\hat{\boldsymbol{\beta}}$. The feature matrix $\mathbf{X}$ is shown with a subset of features highlighted in blue, indicating feature selection.

Feature Selection

Feature Transformation

$$\hat{\mathbf{y}} = \mathbf{X} \hat{\boldsymbol{\beta}}$$

Feature Transformation

Minimize

$$\|\mathbf{X} - \mathbf{W}\mathbf{H}\|_{\text{F}}^2 = \sum_{i,j} (\mathbf{X}_{i,j} - (\mathbf{W}\mathbf{H})_{i,j})^2$$

Feature Transformation

$$\hat{y} = W\hat{\beta}$$

Feature Transformation

- Feature transformation is useful for
 - Information compression
 - Data artifact clean-up
 - Visualization

Feature Transformation

- Change of basis (i.e. “perspective”) for data representation
- Techniques with different priors on data generation process:
 - Singular Value Decomposition (SVD)
 - Principal Component Analysis (PCA)
 - Independent Component Analysis (ICA)
 - Non-negative Matrix Factorization (NMF)

Principal Component Analysis (PCA)

- PCA finds a set of components (eigenvectors) that are orthogonal and capture the maximum variance in data.
- These components form the basis of the new space that the data will be transformed to
- Truncating the components to keep only the first k components gives the best rank- k approximation of X and transforms X to k -dim space

Principal Component Analysis (PCA)

Principal Component Analysis (PCA)

Reconstructing with 1 principal component:

Explained variance: 0.53

Principal Component Analysis (PCA)

Reconstructing with 2 principal components:

Explained variance: 0.84

Principal Component Analysis (PCA)

Reconstructing with 3 principal components:

Principal Component Analysis

- Variance explained

Principal Component Analysis (PCA)

$$\hat{\mathbf{y}} = \mathbf{X} \hat{\boldsymbol{\beta}}$$

$$\hat{\mathbf{y}} = \mathbf{W} \hat{\boldsymbol{\beta}}$$

Principal Component Analysis

- sklearn

```
transformer = PCA(n_components=N)
transformer.fit(X)
transformed_X = transformer.transform(X)
print(transformed_X.shape) #(n_samples, n_components)
```

```
transformer = PCA(n_components=N)
transformed_X = transformer.fit_transform(X)
```
